

**Amendments to the Specification:**

Please replace the paragraph beginning at page 2, line 19 of the amended specification filed April 30, 2007 (originally found at page 19, lines 1-9 of the application) with the following rewritten paragraph:

More particularly, a destination computer 212 at block 502 of Fig. 6 may recognize a need for additional resources in order to accomplish an elevated workload, for instance. Where the destination computer 212 has no standby resources available at block 504, then the destination computer 212 may initiate generation of a deactivation ~~an activation~~ code at block 506 for removing availability. An exemplary ~~activation~~, or deactivation code may include an instruction that is readable by the source computer 222. The deactivation code sent at block 508 is received and processed at block 510. Such processing may include determining the number of standby resources for which the destination computer 212 would have made available.

Please replace the paragraph beginning at page 3, line 2 of the amended specification filed April 30, 2007 (originally found at page 19, lines 10-16 of the application) with the following rewritten paragraph:

At block 512 of Fig. 6, it is determined if the source computer 222 ~~212~~ can relinquish availability to the requested number of standby entitlements. Namely, it is determined at block 512 if the source computer 222 has resources available for transfer. Where the source computer 222 cannot transfer entitlements, the destination computer 212 may receive a failure signal at block 516 that has been generated at block 514. Alternatively, the source computer 222 will relinquish access to the standby resources at block 518 where appropriate. The source computer 222 may further generate a signature at block 520 in response to and evidencing the relinquishment.
